Appendix 3: Case-crossover results

Appendix A3.1: Case-crossover meta-analyses

Every model controlled for average temperature, average temperature difference (current minus previous day), average humidity, average pressure, extremes of hot and cold (coldest and warmest 1% of days), day of the week and public holiday (yes/no). Models of admission variables also included an indicator variable for the day after a public holiday. Models in Canberra included an indicator for the 15th of the month. Pollutants effects are the average over lagged days 0 and 1.

Nine analyses from Canberra were excluded because they were based on less than 60 days of data.

A random effects meta-analysis was used to combine the effects across cities (using R function `met_uni_R`). We used a test of heterogeneity to find differences across cities and used the related I-squared which is interpretable as the proportion of total variation in the relative risks that is due to heterogeneity between cities (Higgins and Thompson, 2002).

All results are shown to a one-unit increase, although the tabulated meta-analysis results are shown to both a one-unit increase and a one-IQR increase (using the mean IQR across cities, see Table CM.0).

Table CM.0: Inter-quartile ranges of pollutants by city

Pollutant	City							Mean*
	Auckland	Brisbane	Canberra	Christchurch	Melbourne	Perth	Sydney	
24-hour average bsp	-	0.11	0.37	-	0.18	0.13	0.16	0.19
24-hour average PM ₁₀	-	6.51	-	10.29	7.58	6.38	6.82	7.53
24-hour average PM _{2.5}	-	4.04	-	-	3.79	3.17	4.14	3.78
24-hour average NO ₂	5.92	4.58	5.16	4.77	6.26	4.05	5.26	5.14
1-hour maximum NO ₂	9.62	8.86	9.81	8.20	9.81	8.40	8.17	8.98
24-hour average SO ₂	2.78	1.27	-	2.16	-	-	0.58	1.70
1-hour maximum SO ₂	-	5.76	-	8.22	-	-	2.24	5.40
8-hour average O ₃ (max)	7.45	9.18	9.52	-	8.87	6.84	11.13	8.83
4-hour maximum O ₃ (max)	7.77	10.02	9.71	-	8.94	6.81	11.58	9.14
1-hour maximum O ₃	7.77	11.36	9.97	-	9.20	7.85	12.80	9.83
8-hour average CO (max)	1.36	0.84	1.02	0.85	0.76	0.55	0.64	0.86

* Mean of IQRs across cities

Meta-analysis of case-crossover results

Updated analyses including admissions results from Canberra. All tables are split in two because of the number of pollutants.

Appendix A3.2: Case-crossover matching on other air pollutants and temperature

In order to determine the independent pollution effects we further investigate the significant relationships found in the meta-analysis using matching. The design is a replication of the analysis of Schwartz, 2004, “Is the association of airborne particles with daily mortality confounded by gaseous air pollutants?” Used the same case-crossover models as in the meta-analysis, that is, every model controlled for average temperature, average temperature difference (current minus previous day), average humidity, average pressure, extremes of hot and cold (coldest and warmest 1% of days), day of the week and public holiday (yes/no). Models of admission variables also included an indicator variable for the day after a public holiday. Models in Canberra included an indicator for the 15th of the month. Pollutants effects are the average over lagged days 0 and 1.

Matched using 28-day windows (with one day exclusion window) and then pollutant matches:

- ◆ PM₁₀ (lags 0 and 1) 24-hour average within 3 µg/m³
- ◆ PM_{2.5} (lags 0 and 1) 24-hour average within 2 µg/m³
- ◆ bsp (lags 0 and 1) 24-hour average within 0.1 10⁻⁴.m⁻¹
- ◆ SO₂ (lags 0 and 1) 24-hour average within 0.5 ppb
- ◆ SO₂ (lags 0 and 1) 1-hour average within 1 ppb
- ◆ O₃ (lags 0 and 1) 8-hour average within 2 ppb
- ◆ NO₂ (lags 0 and 1) 24-hour average within 1 ppb
- ◆ NO₂ (lags 0 and 1) 1-hour average within 1 ppb
- ◆ CO (lags 0 and 1) 8-hour average within 0.5 ppm
- ◆ Temperature lags 0 and 1 within 1 degree Celsius.

Only examined pollutants that showed a statistically significant increase using the meta-analysis, and only matched with other pollutants that showed a significant increase. The pollutants PM₁₀, PM_{2.5} and bsp were not matched because of a high degree of similarity.

The cells in each table show the increase in mortality for a one IQR increase in pollutant.

Differences from Joel’s method:

- ◆ Joel used non-linear apparent temperature as a covariate; we use linear temperature and include extreme hot and cold.
- ◆ Joel used maximum daily O₃; we use 8-hour maximum
- ◆ Joel used 24-hour average CO and matched in 0.03 ppm; we use 8-hour average maximum matched within 0.5 ppm
- ◆ Joel did not match on temperature.

Table MM.1 Cardiac admissions 15-64 yrs

Pollutant	Match	Inc	95% CI
24-hour average NO ₂	24-hour average bsp	3.3	1.5, 5.3
	8-hour average CO (max)	-0.0	-1.6, 1.5
	Average temperature	2.4	0.9, 4.0
	Unmatched	2.2	0.9, 3.4

Appendix A3.4: Case-crossover single-city seasonal analysis

Results are stratified by warm and cool season, a separate case-crossover analysis is run for each season in each city. Warm season in November to April, Cool season is May to October. Results shown for a one-IQR increase. Estimates from a case-crossover analysis used average of lag 0 & 1 pollutant.

Appendix A3.5: Case-crossover seasonal meta-analysis and seasonal Leave-One-City-Out sensitivity analysis

The results here are stratified by warm and cool season, so a separate case-crossover analysis is run for each season in each city. Warm season is November to April, and Cool season in May to October. Results shown for a one-IQR increase. Estimates from a case-crossover analysis used average of lag 0 & 1 pollutant.

* Results for ozone for Brisbane, Sydney, Melbourne and Perth for the leave-one-city-out analysis included data for Canberra and Auckland. Results for Australian cities only and meta-analysis include data for Brisbane, Melbourne, Perth and Sydney only.

Appendix 4: GAM (lag 0-1) results and comparison to case-crossover results

Every model controlled for long-term trend, season, average temperature, average temperature difference (current minus previous day), average humidity, average pressure, extremes of hot and cold (coldest and warmest 1% of days), flu epidemics, day of the week and public holiday (yes/no). Models of admission variables also included an indicator variable for the day after a public holiday. Models in Canberra included an indicator for the 15th of the month. Pollutants effects are the average over lagged days 0 and 1.

A random effects meta-analysis was used to combine the effects across cities (using R function `met_uni_R`). We used a test of heterogeneity to find differences across cities and used the related I-squared which is interpretable as the proportion of total variation in the relative risks that is due to heterogeneity between cities (Higgins and Thompson, 2002).

All results are shown to a one-unit increase, although the tabulated meta-analysis results are shown to both a one-unit increase and a one-IQR increase.

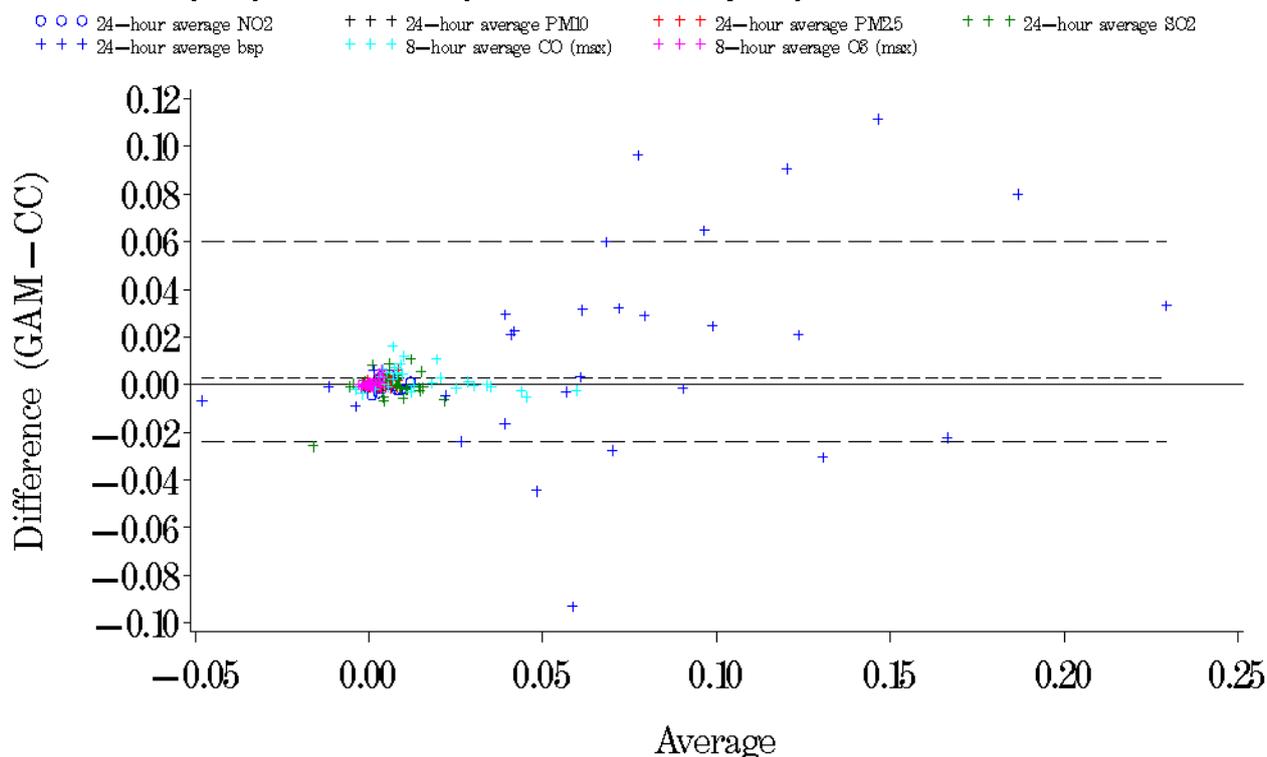

Figure GM.1: Agreement between city-level GAM and case-crossover (CC) estimates (Bland-Altman plot)

Long dotted lines show central 95th percentile, short dotted lines show mean, solid line at zero (perfect agreement).

The plot is based on $n=1012$ estimates. Average difference between methods=0.014, t-statistic=8.04, p-value<0.0001. Some evidence that GAM estimates are, on average, greater than case-crossover estimates, but the difference is small. The biggest difference is in Perth for Cardiac failure admissions 65+ yrs and 24-hour bsp, GAM=0.68, CC=0.17.

Figure GM.2: Agreement between meta-analysis GAM and case-crossover (CC) estimates (Bland-Altman plot)

Long dotted lines show central 95th percentile, short dotted lines show mean, solid line at zero (perfect agreement).

Based on $n=210$ estimates. Biggest differences for bsp. Average difference between methods=0.0028, t -statistic=2.33, p -value=0.02. So some evidence that GAM estimates are, on average, greater than case-crossover estimates, but the difference is very small.

Appendix 5: Distributed lag results

Appendix A5.1: Harvesting meta-analysis results

In this analysis we used an unconstrained distributed lag over 0 to 40 days to look at the longer-term effects of air pollution. The advantages of this method (above a polynomial method) are that the total sum is an unbiased estimate of the overall risk, and it is straightforward to combine estimates across cities using a random effects meta-analysis. The main disadvantage of this method is that there is no pictorial estimate of the overall shape.

Every model controlled for long-term trend, season, average temperature, average temperature difference (current minus previous day), average humidity, average pressure, extremes of hot and cold (coldest and warmest 1% of days), day of the week and public holiday (yes/no). Models of admission variables also included an indicator variable for the day after a public holiday. Models in Canberra included an indicator for the 15th of the month. In every city but Canberra we also controlled for flu epidemics. We used penalised splines for the covariates of: trend/season (4df per year) temperature (3 df), temperature difference (3 df), humidity (3 df), pressure (3 df) and flu epidemics (4 df).

A random effects meta-analysis was used to combine the effects across cities (using the R function `met_uni_R`). We used a test of heterogeneity to find differences across cities and used the related I-squared which is interpretable as the proportion of total variation in the relative risks that is due to heterogeneity between cities (Higgins and Thompson, 2002).

All results are shown to a one-unit increase, although the tabulated meta-analysis results are shown to both a one-unit increase and a one-IQR increase (using the mean IQR across cities).

The increase in respiratory admissions 5-14 yrs in Melbourne due to NO₂ is much higher than other cities. The increase in respiratory admissions 65+ yrs in Melbourne due to PM₁₀ is very much higher than in other cities. Both results have been highlighted in the tables in red text.

Distributed lag single city and meta-analysis results

Appendix A5.2: Distributed lag Leave-one-city-out sensitivity analyses

Tables show meta-analyses of distributed lag results after leaving out each city in turn. Tables also show the results of only using Australian or New Zealand cities. Results are increases in events, shown for a one-IQR increase in pollutant.
